**Significance of the Positive Crossmatch Test in Kidney  
Transplantation**

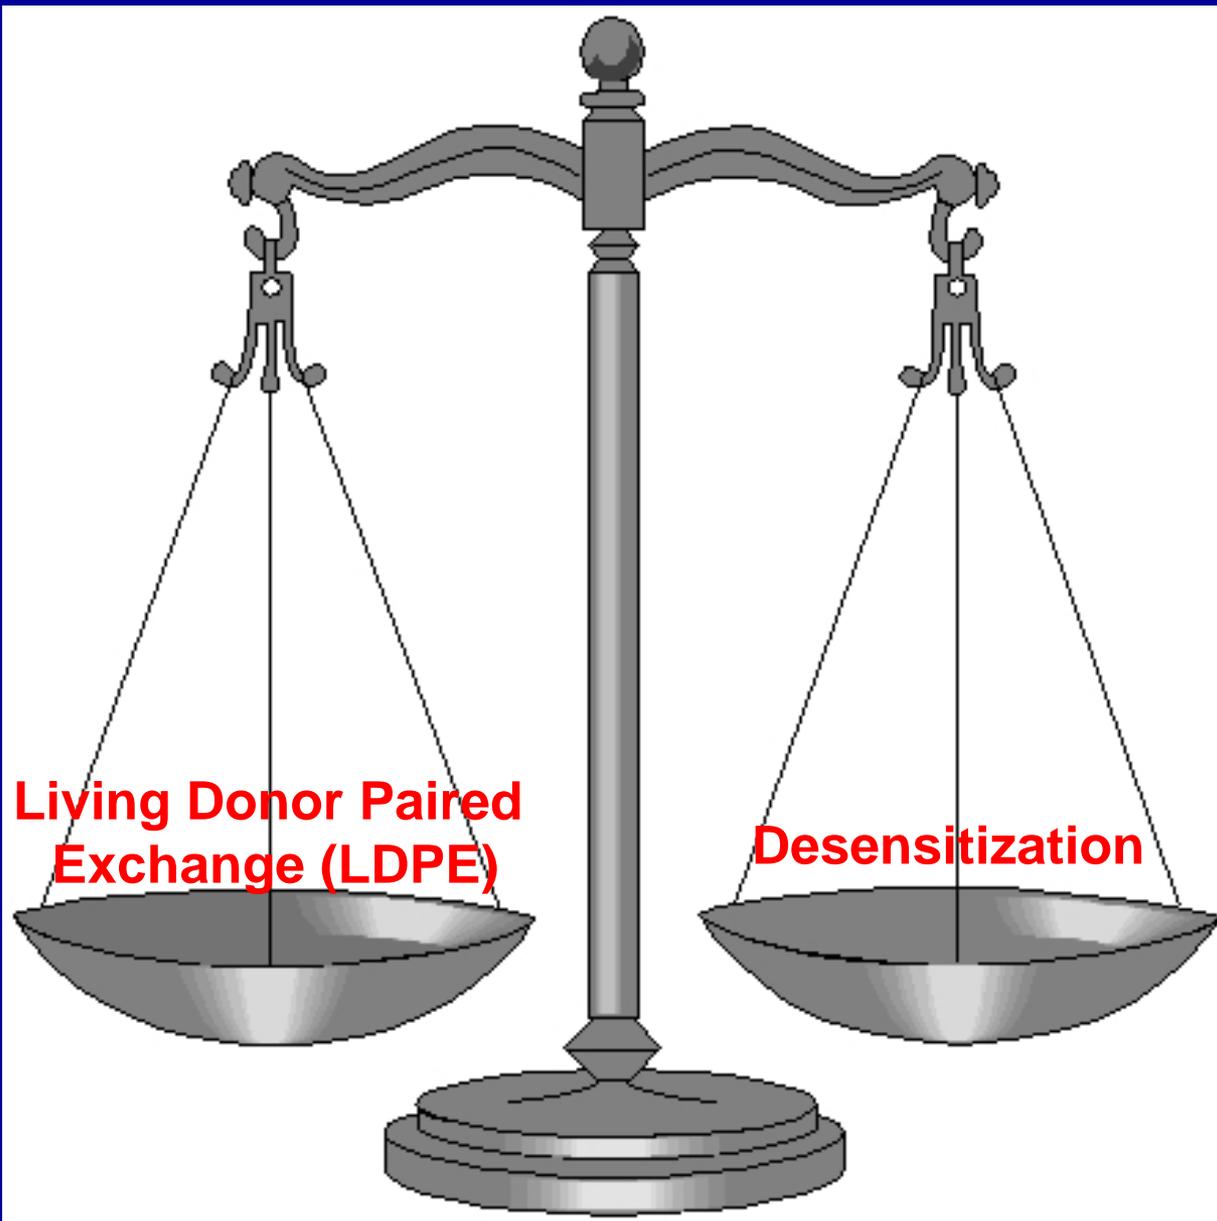

Ramon Patel, M.R.C.P., and Paul I. Terasaki, Ph.D.

- Pre-transplant crossmatch (CMX) with donor lymphocytes has been standard of practice
- Positive CDC CXM → contraindication to transplant
- Modifications to CXM → increased transplant success rates but relegated increased number of patients to longer waiting times

# Sensitization Increases Median Waiting Time

- In U.S. 30% of patients on waiting list are sensitized (transfusion, pregnancy, transplant)
- 6.5% of highly sensitized patients (PRA >80%) receive a transplant per year

**Living Donor Paired  
Exchange (LDPE)**

**Desensitization**

# Donor Specific Antibody

Panel Reactive Antigen

<p><b>Low DSA</b> <b>Low PRA</b> <b>O Donor</b> Easy for LDPE and Desensitization</p>	<p><b>High DSA</b> <b>Low PRA</b> <b>O Donor</b> Difficult for Desensitization</p>
<p><b>Low DSA</b> <b>High PRA</b> <b>O Donor</b> LDPE → Desensitization</p>	<p><b>High DSA</b> <b>High PRA</b> <b>AB Donor</b> Difficult for LDPE and Desensitization (LDPE + Desensit)</p>

## Desensitization

```
graph TD; A([Desensitization]) --> B((Living Donor Transplant:  
Attenuate the humoral alloimmune response so recipient becomes crossmatch negative against a specific donor)); A --> C((Deceased Donor Transplant:  
Attenuate the humoral alloimmune response (Δ %PRA) making it more likely a recipient will receive a deceased donor transplant));
```

### Living Donor Transplant:

Attenuate the humoral alloimmune response so recipient becomes crossmatch negative against a specific donor

### Deceased Donor Transplant:

Attenuate the humoral alloimmune response ( $\Delta$  %PRA) making it *more likely* a recipient will receive a deceased donor transplant

# General Approach to Desensitization

1. Remove or neutralize anti- IgG
2. Prevent formation of new anti- IgG before transplantation
3. Transplant when crossmatch (CMX) is negative
4. Prevent formation of new anti- IgG after transplantation
5. Rapidly diagnose and reverse acute AMR if it occurs

Rituximab

## Immunoadsorption

Plasma is separated from whole blood by filtration or centrifugation. The plasma is then processed through an immunoadsorbent column and re-infused to the patient. There are no volume losses and thus no need for replacement fluids.

**Advantage of Protein A Column over Plasmapheresis:  
it only removes IgG**

# Immunoadsorption (IA): Highly Sensitized

- **1996: Kings College London<sup>1</sup>**
  - CXM + → - with IA pre transplant but 70% AR and 53% graft survival at last follow up
- **1990-2003: Vienna group<sup>2</sup>**
  - 40 highly sensitized patients → IA pre and post deceased donor Tx + pre ATG x 10-14d
  - 73% 3-y survival graft survival; 20% cellular AR; 33% humoral AR

## Desensitization Therapies

```
graph TD; A[Desensitization Therapies] --> B[High Dose IVIg]; A --> C[Plasmapheresis]; A --> D[Rituximab]; A --> E[Immunoadsorption];
```

## Immunoadsorption

### High Dose IVIg

- Pooled from multiple donors
- Blocks Fc receptors on mononuclear phagocytes
- Anti-idiotypic effects
- Inhibits CD19 expression on activated B cells
- Inhibits complement
- Inhibits alloreactive T cells

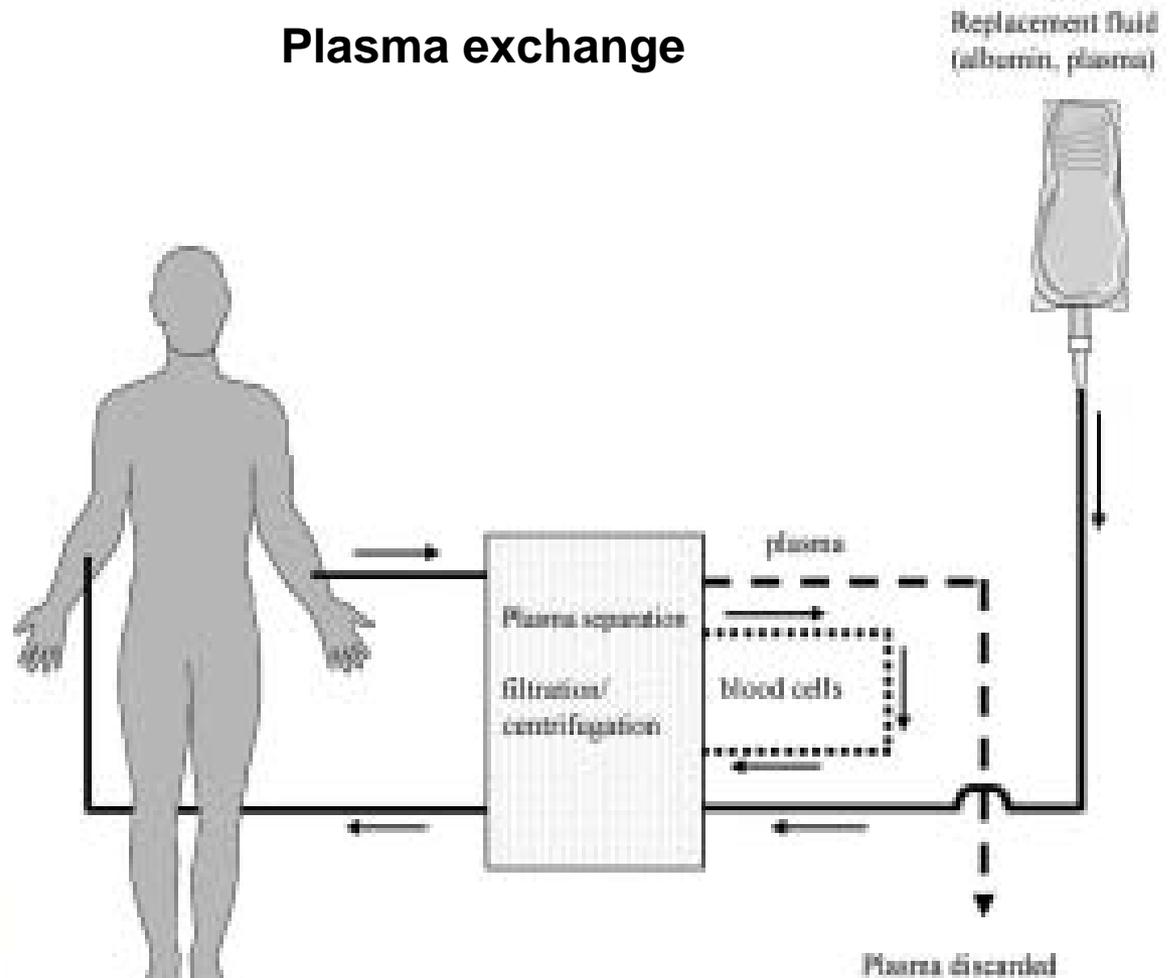

### Plasmapheresis

- Plasma separated from whole blood by filtration/centrifugation and discarded
- Replacement of plasma with 5% albumin + isotonic saline/FFP
- Removes anti-HLA antibodies
- Immediately followed by low-dose IVIg

### Rituximab

- Chimeric murine/human monoclonal Ab against CD20 Ag on surface of B cells
- Not expressed on plasma cells
- Prevents formation of new alloantibody-producing plasma cells
- Inhibits B-cell driven Ag presentation and costimulation of T cells

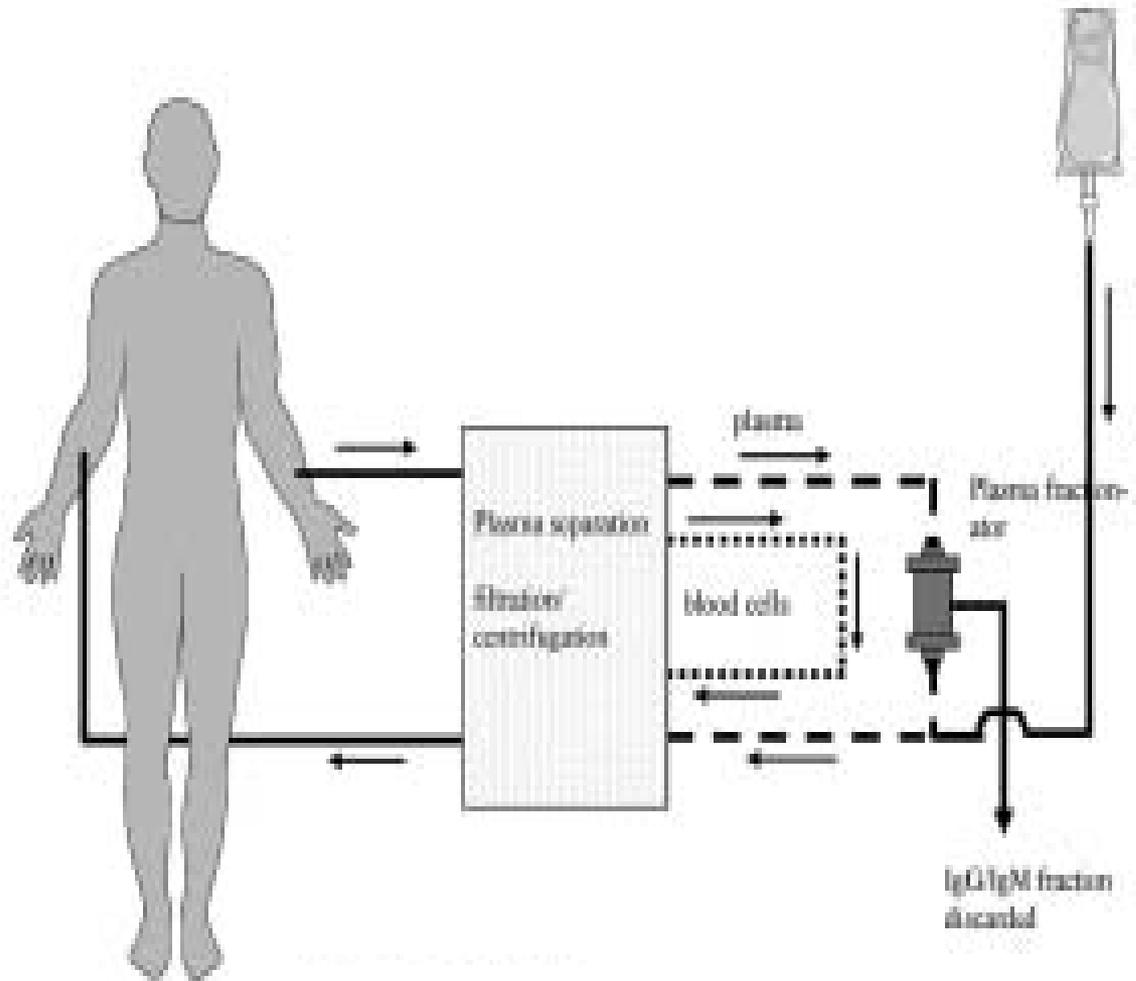

# Plasma exchange

**FIGURE 1.** Plasma exchange. Plasma is separated from whole blood by filtration or centrifugation and then discarded. The whole plasma volume is replaced by Ringer's solution and albumin and/or fresh-frozen plasma.

## Double-filtration plasma exchange

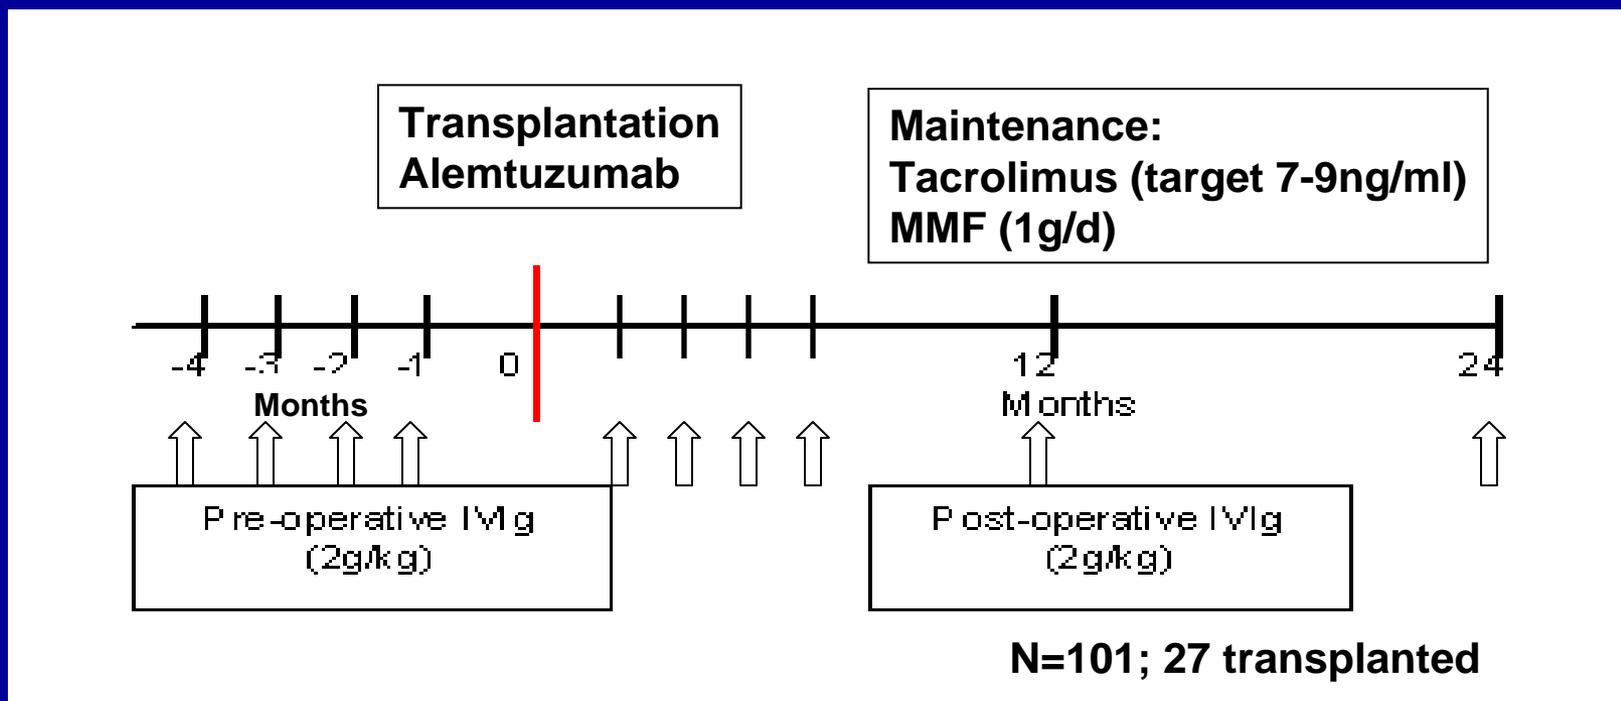

Replacement fluid  
(albumin + Ringers)

**FIGURE 2.** Double-filtration plasmapheresis. Plasma is separated from whole blood by filtration. The plasma is then passed through a second filter where substances with molecular weights of 170,000 (IgG) and 1,000,000 (IgM) are filtered out and discarded. Only the volume of the discarded immunoglobulin fraction is replaced by Ringer's solution and albumin.

# NIH IG02 Study

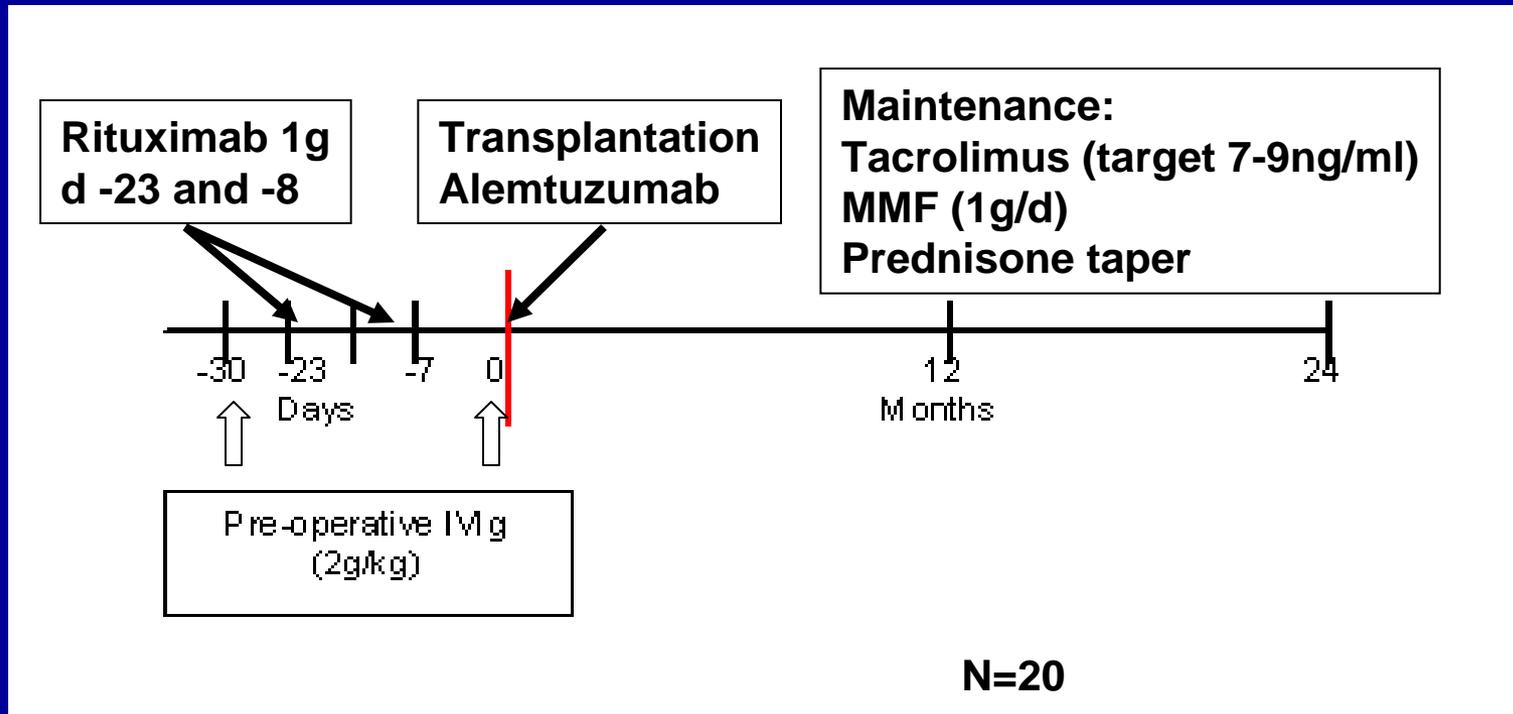

## IVIg is superior to placebo in reducing anti-HLA Ab levels and improving transplantation rates in the highly sensitized

IVIg total dose not >180g

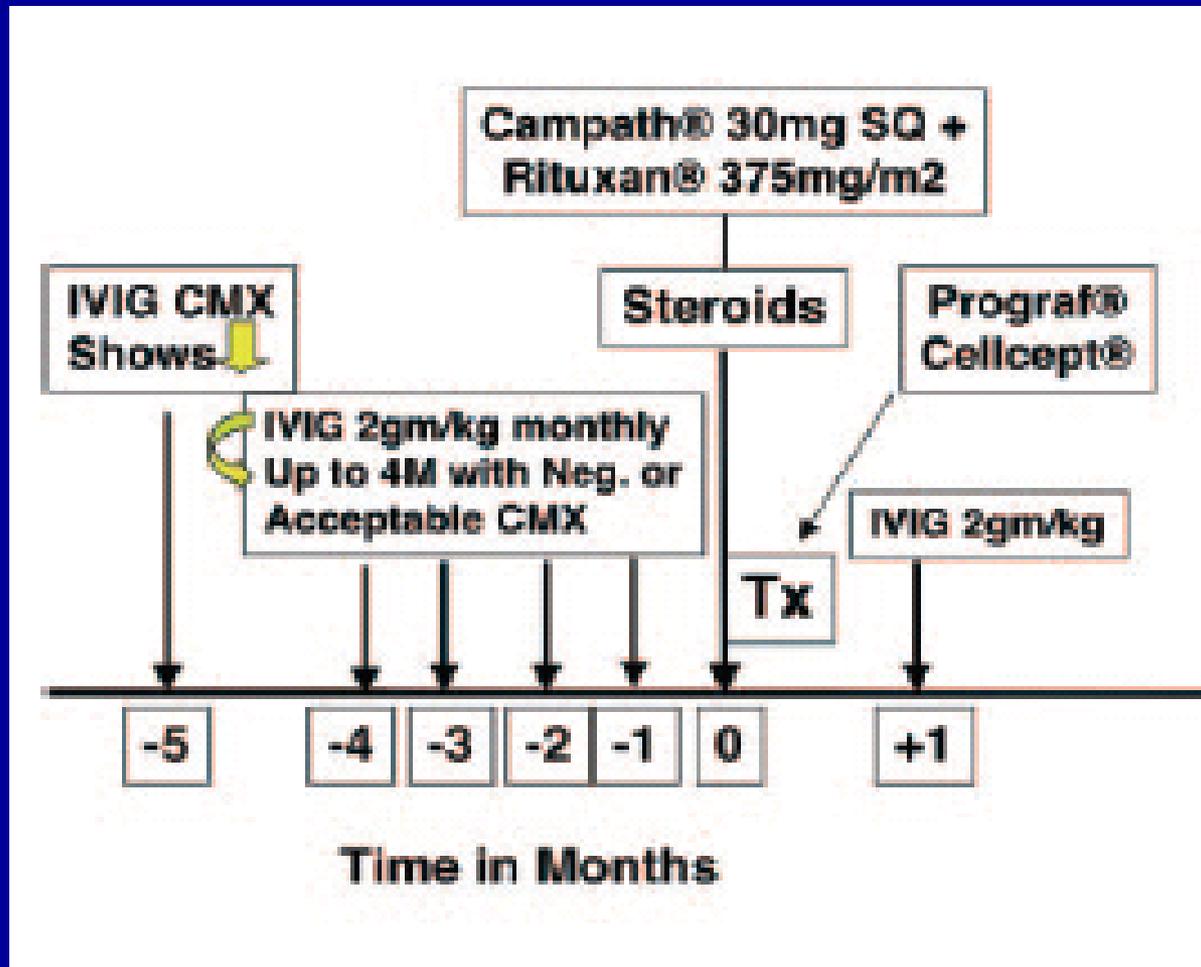

- 35% of IVIg v 17% placebo → transplant
- AR 9/17 IVIg; 1/10 placebo

# Combining Rituximab and High Dose IVIg Reduces the Total Dose of IVIg

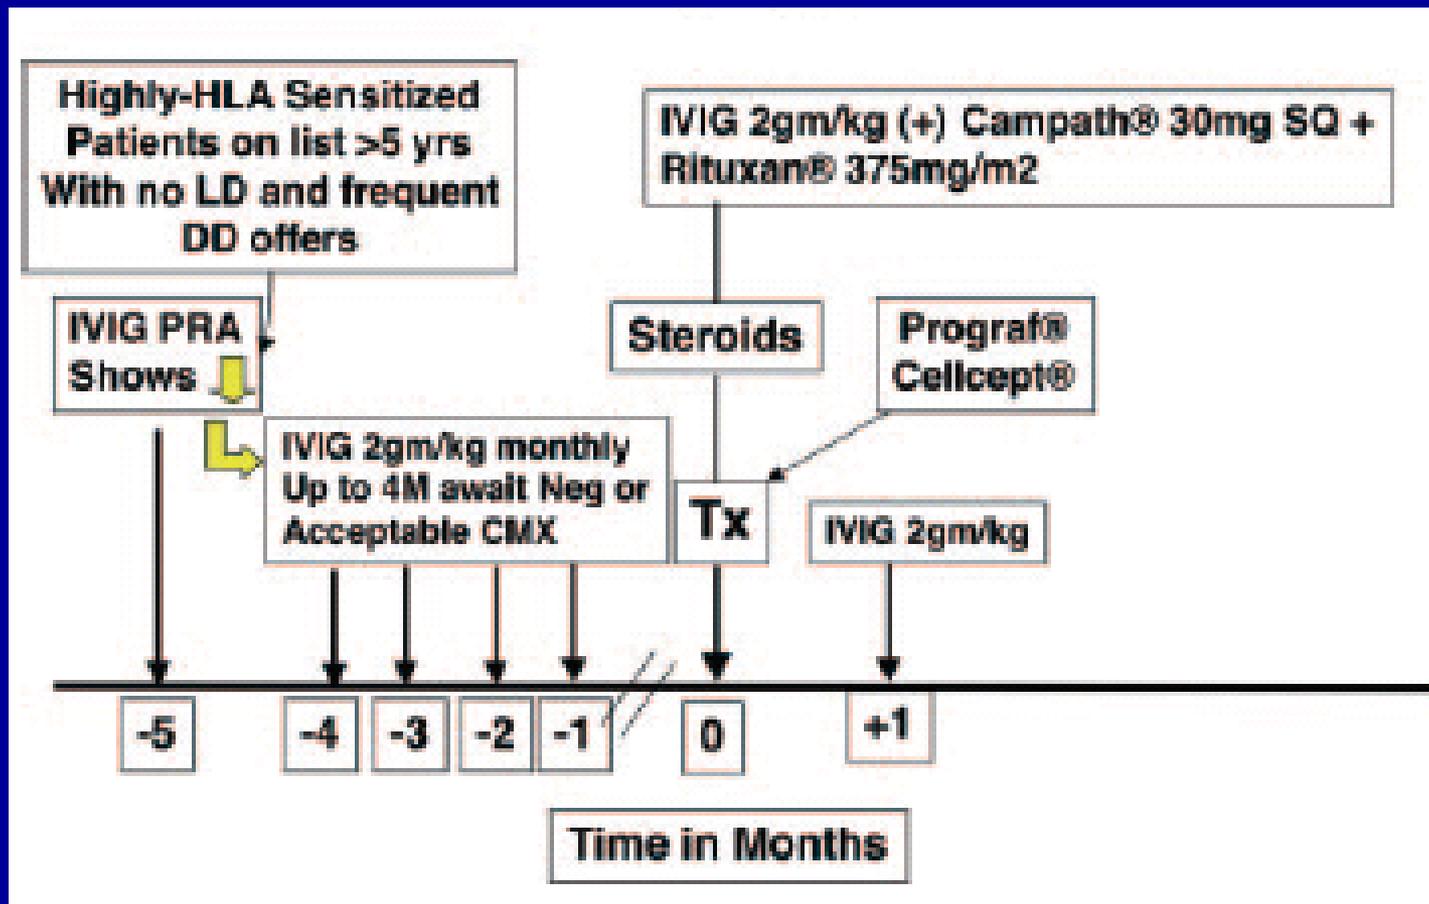

- PRA ↓ to 44% ± 30% (from 77% ± 19%)
  - 16/20 transplanted; mean time to transplant = 5±6m
  - AR = 50% (31% AMR); patient and graft survival at 1y = 100 and 97%
- Vo AA, Jordan SC NEJM 2008, 359:242

# Cedar-Sinai Protocol Using High Dose IVIg : Positive CMX Living Donor Desensitization

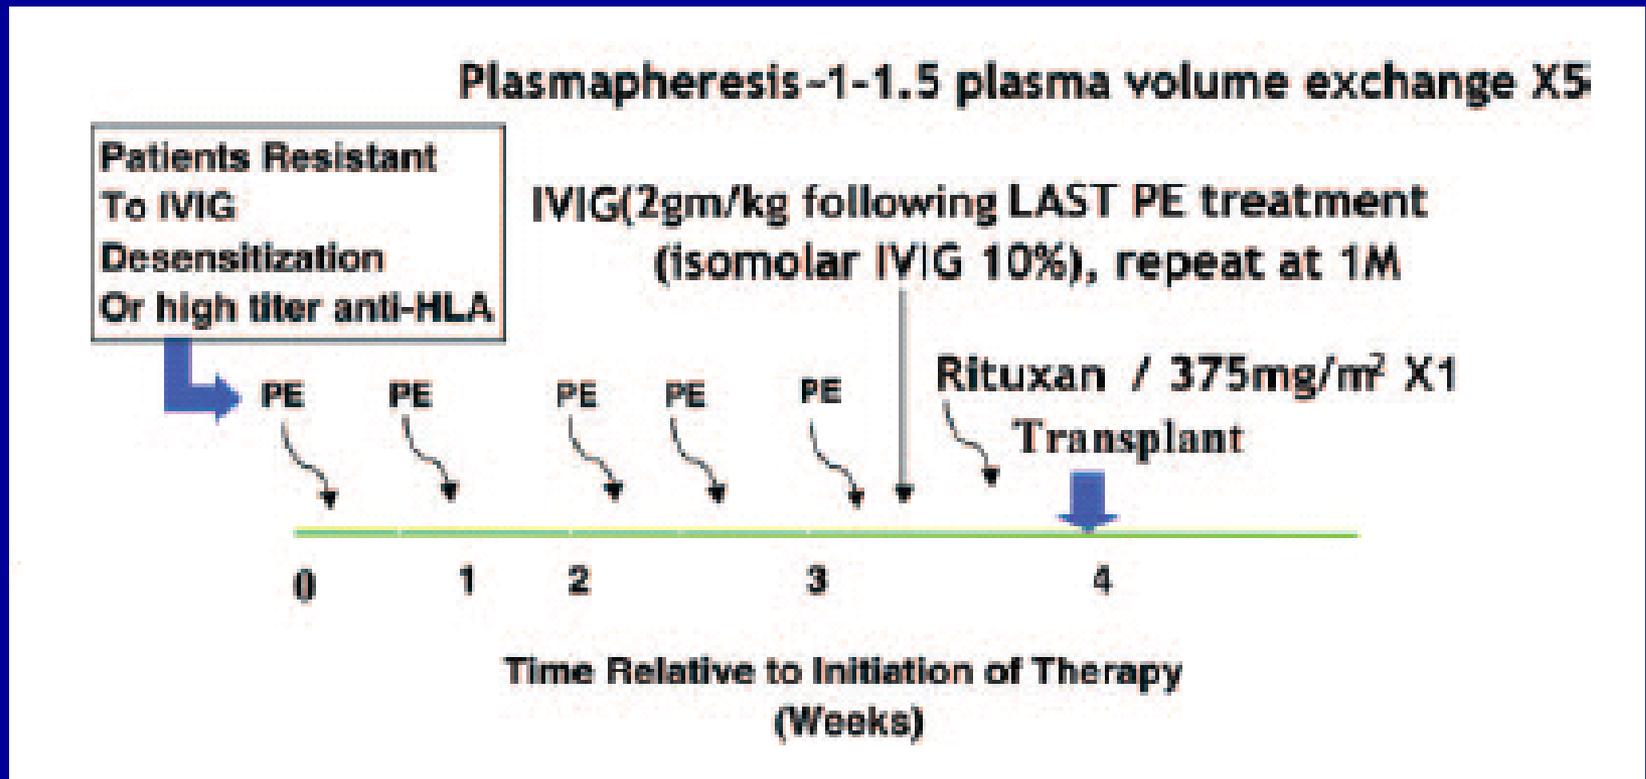

IVIg total  
dose not  
>140g

# Cedar-Sinai Protocol Using High Dose IVIg : Positive CMX Deceased Donor Desensitization

# Cedar-Sinai Protocol Using High Dose IVIg + Rituximab in Highly Sensitized Patients Resistant to IVIg

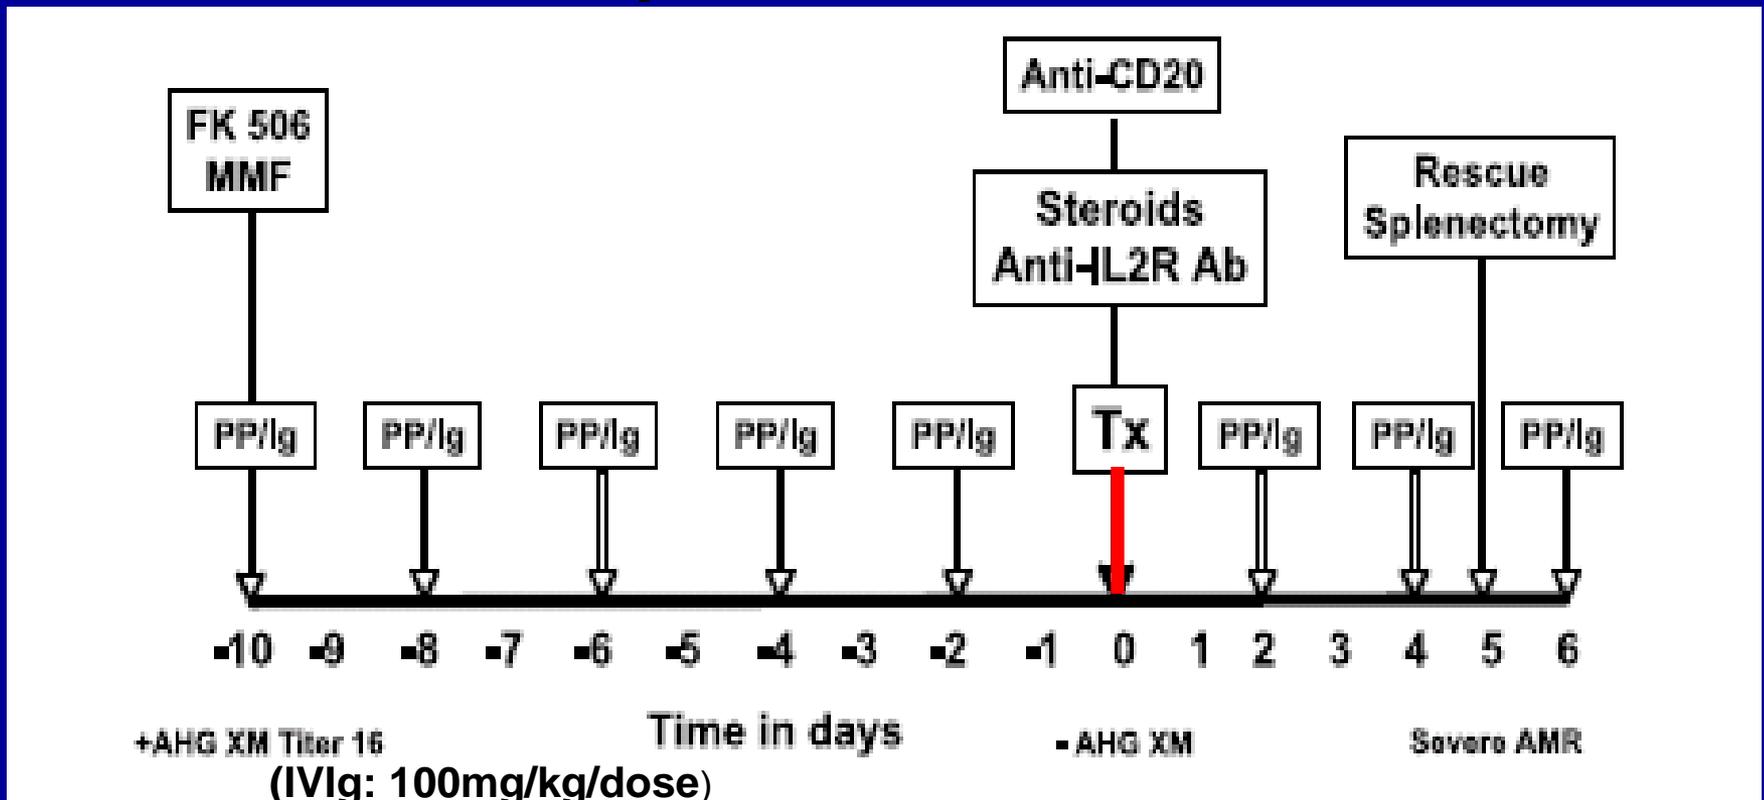

If CMX is negative or acceptable T cell  
(flow CMX <250 channel shifts) → Transplantation

## IVIg + Rituximab: Rejection and survival

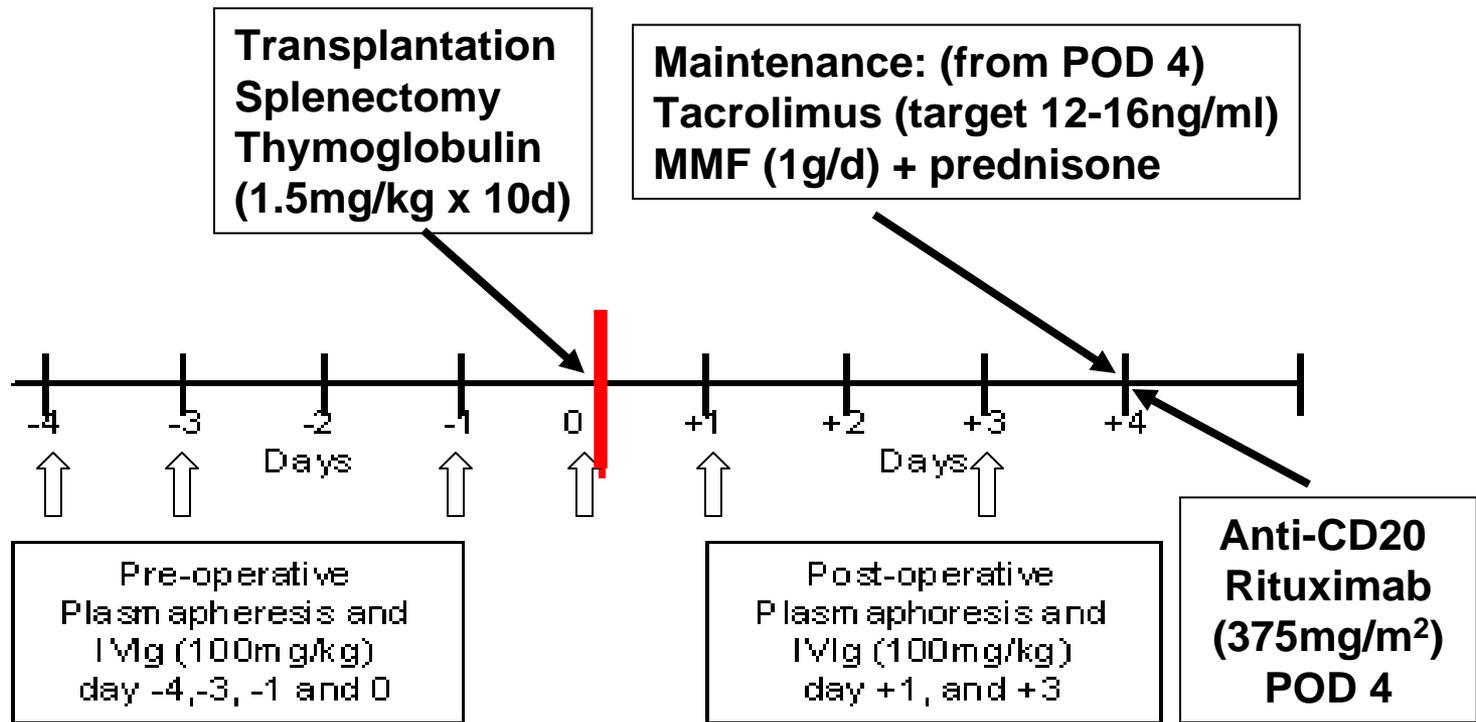

- July 2006 - February 2009: 76 HLA-sensitized (HS) patients received KTX after desensitization using:
  - IVIG 2 g/kg (days 1 and 30)
  - Rituximab (1 g, day 15)
- 76 HS CMX+ treated patients (31 LD/45 DD) → TX
- Significant ↓ in T-cell flow CMXs from pretreatment to time of transplant.
- Time on wait list for DD recipients was ↓ from 95±6 months to 4.2±4.5months after treatment.
- 37% → acute rejection (29% C4d+/8% C4d-).
- Patient and graft survival at 24 months = 95% and 84%.

# Johns Hopkins Protocol: CXM +

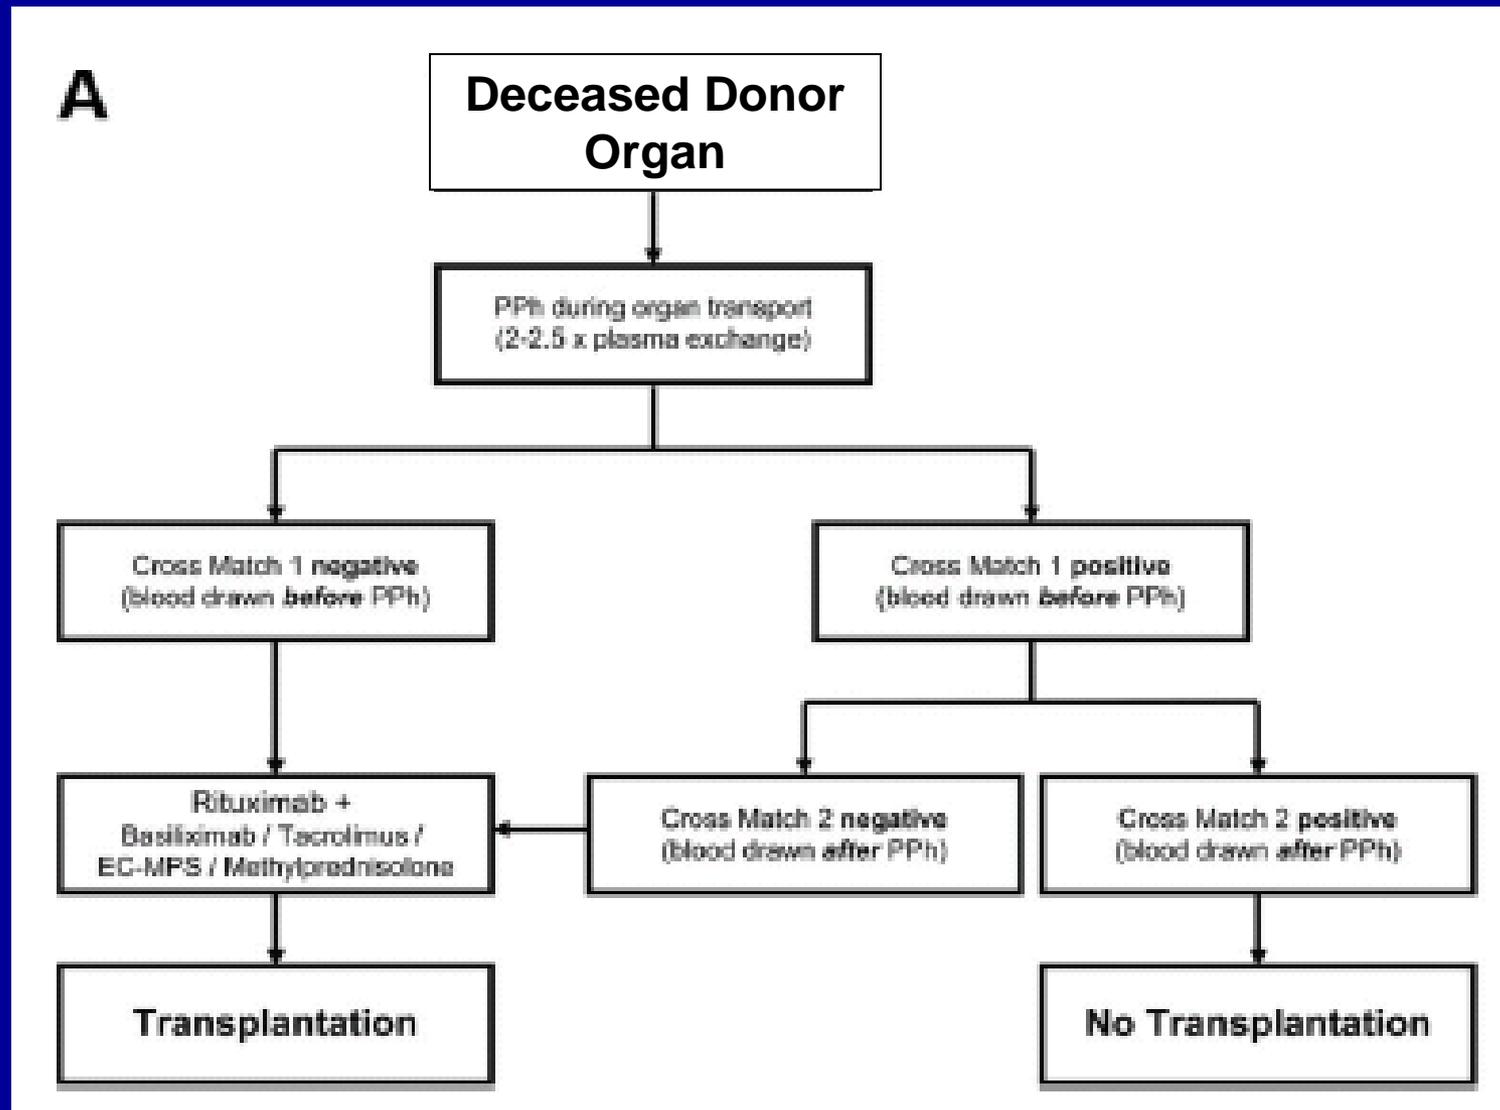

- If recipient begins with a positive AHG CDC crossmatch (+AHG XM) titer of 16.
- Average decrement of one dilution per PP/IVig. 5 treatments → -AHG XM.
- In selective high-risk cases anti-CD20 given night before transplant.
- Induction includes an anti-IL2 blockade and high-dose steroids.
- Several posttransplant PP/IVig treatments are performed by protocol.
- About 5% of +XM patients require rescue splenectomy for severe AMR.

# Mayo Clinic Protocol

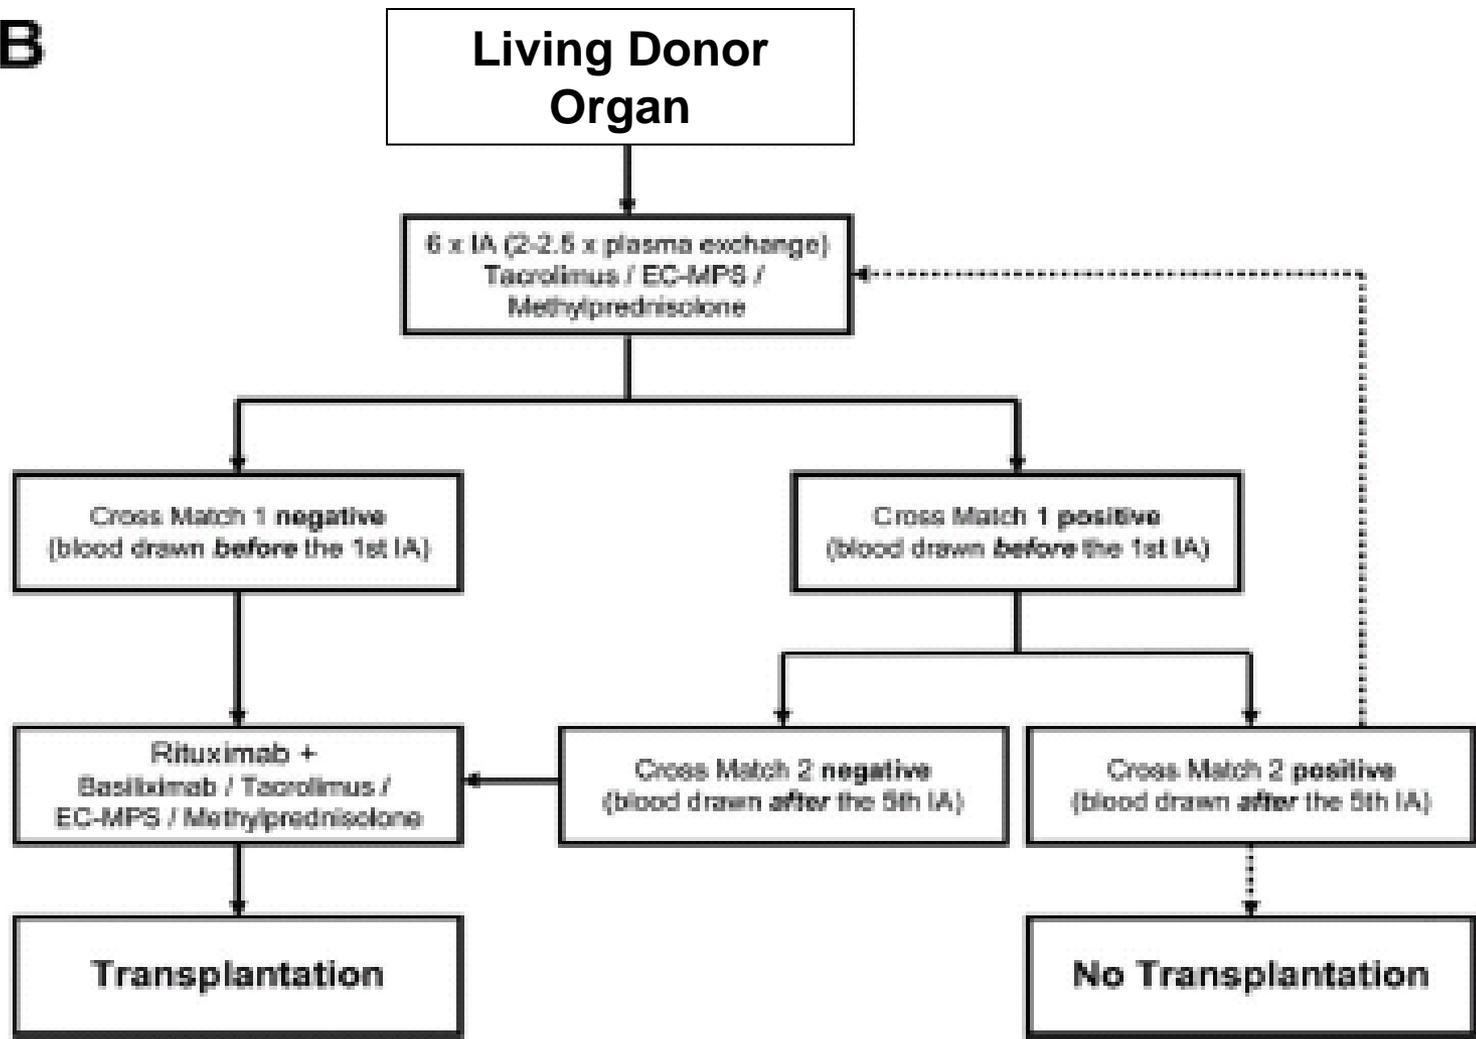

- N=14 + CXM to living donor
- AMR 29% but all reversible

# Eurotransplant Algorithm Highly Sensitized

# Eurotransplant Algorithm: Highly Sensitized

**B**

# High-Dose IVIg vs. PP + CMV-Ig

## High-Dose IVIg

### Advantages:

- Less expensive
- Success in living and deceased donor transplant
- Easy and safe (dialysis)
- Long-lasting desensitization in most cases

## High-Dose IVIg

### Disadvantages:

- Non- and incomplete responders (approx 10%)
- May interfere with DSA assays
- Antibody removal slower vs. PP + CMV-Ig
- Some IVIg products have toxicity (sucrose, saline)
- Fever, chills, H/A, anaphylaxis, thrombosis, nephrotoxicity (use isotonic)

# High-Dose IVIg vs. PP + CMV-Ig

## PP + CMV-Ig

### Advantages:

- Highly effective
- Few non-responders
- DSA easy to follow
- Kinetics of DSA removal predictable
- Also removes anti-ABO-A or anti-ABO-B antibodies allowing potential transplantation across 2 incompatible barriers

## PP + CMV-Ig

### Disadvantages:

- Expensive
- Labor intensive
- Not useful if no living donor
- DSA can return post transplant
- Transplant must follow treatment or possible rebound
- Depletion of clotting factors, hypocalcemia, fever, chills

# Johns Hopkins Protocol: ABO incompatible

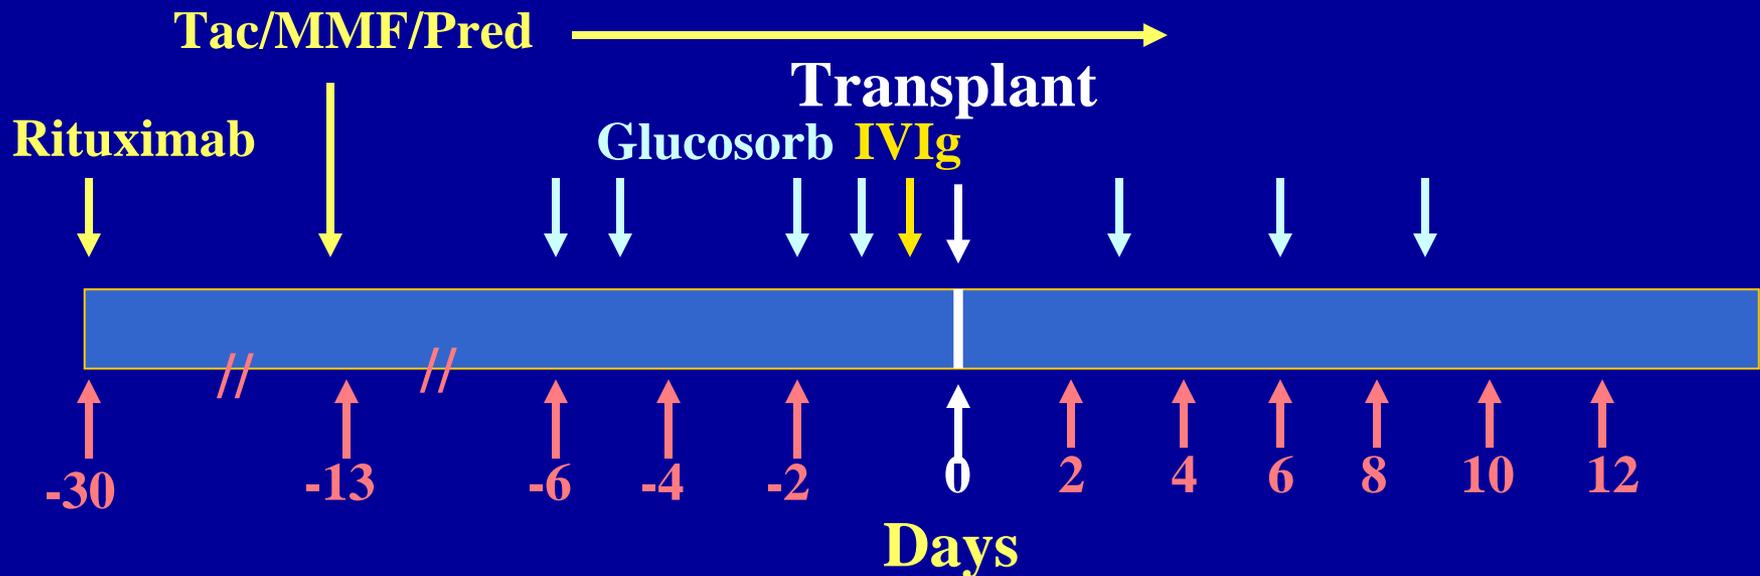

**TABLE 1.** The number of planned pre- and posttransplant PP/IVIg treatments correlate with the starting isohemagglutinin titer

Starting isoagglutinin AHG titer	Pretransplant PP/IVIg treatments	Posttransplant PP/IVIg treatments
<16	2	2
16–32	3	2–3
64	4	3
128	5–6	4
256	7–8	4
512	9–10	5
>512	>10	6

PP, plasmapheresis; AHG, anti-human globulin.

- **Pre-op:** Alt day PP (COBE Spectra centrifuge-driven cell separator) → CMVlg (100mg/kg) and FK506 + MMF at time of 1<sup>st</sup> PP/CMVlg as per table
- Goal AHG titer ≤ 16 at time of Tx
- **Peri-op:** Steroids and daclizumab, hold FK506 am of surgery
- **Post-op:** FK506/MMF/steroids (wean to 20mg/d at d/c)
- Alt day PP/CMVlg as per table if titers fail to fall
- Protocol bx at 1, 3, 6, 12 months; 15% → AHR; survival = other LRD Tx

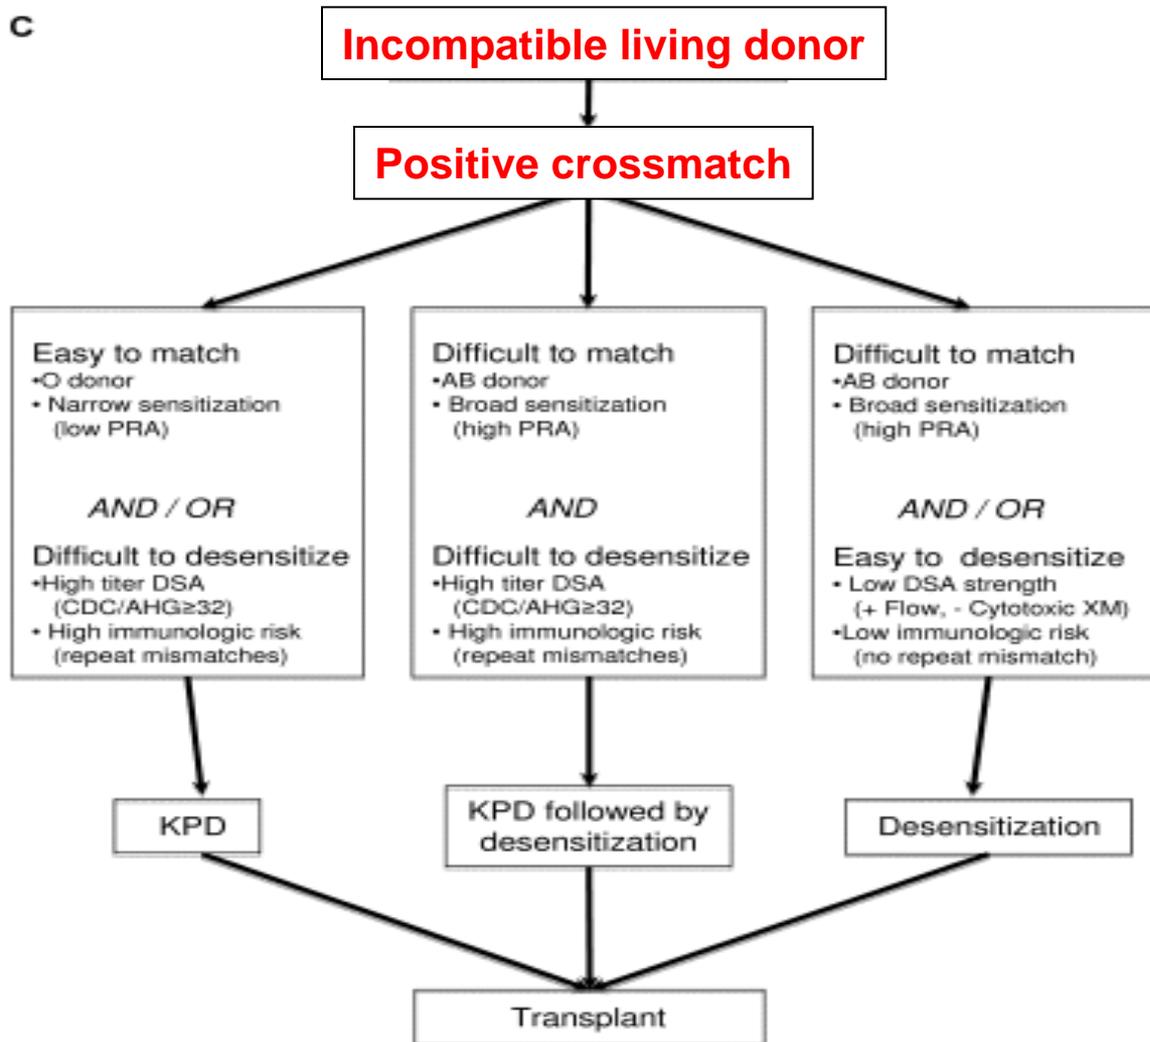

# Swedish Protocol: ABO Incompatible

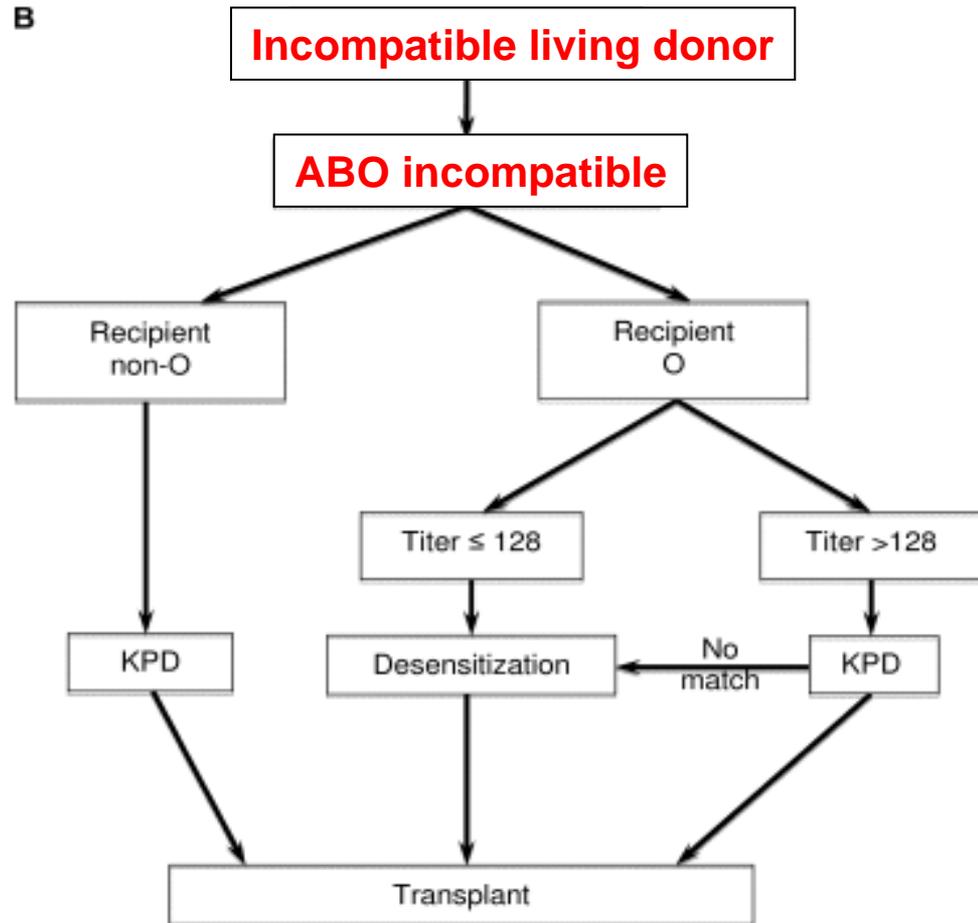

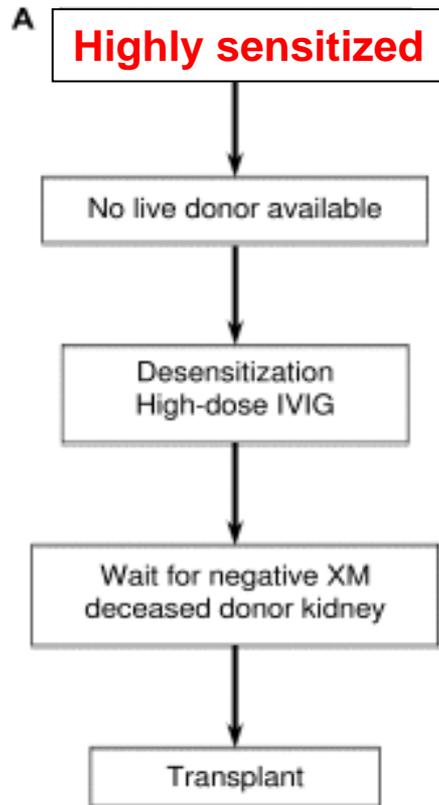

- **Pre-op:** Rituximab (375mg/m<sup>2</sup>) d-30; Tac/MMF/Pred d-14
- Glucosorb IA d-6, -5, -2, -1 to target IgG titer <1:8 (if target titer not achieved 4 more IA over 1 w pre-op or IVIg (0.5g/kg) after last IA)
- **Post-op:** Glucosorb IA d 3, 6 and 9 with additional IA if titers >1:16
- Restricted to patients with titers <1:128
- 3-y outcomes equivalent to LRD; no ↑ AR

# Desensitization versus LDPE

c

# Desensitization versus LDPE

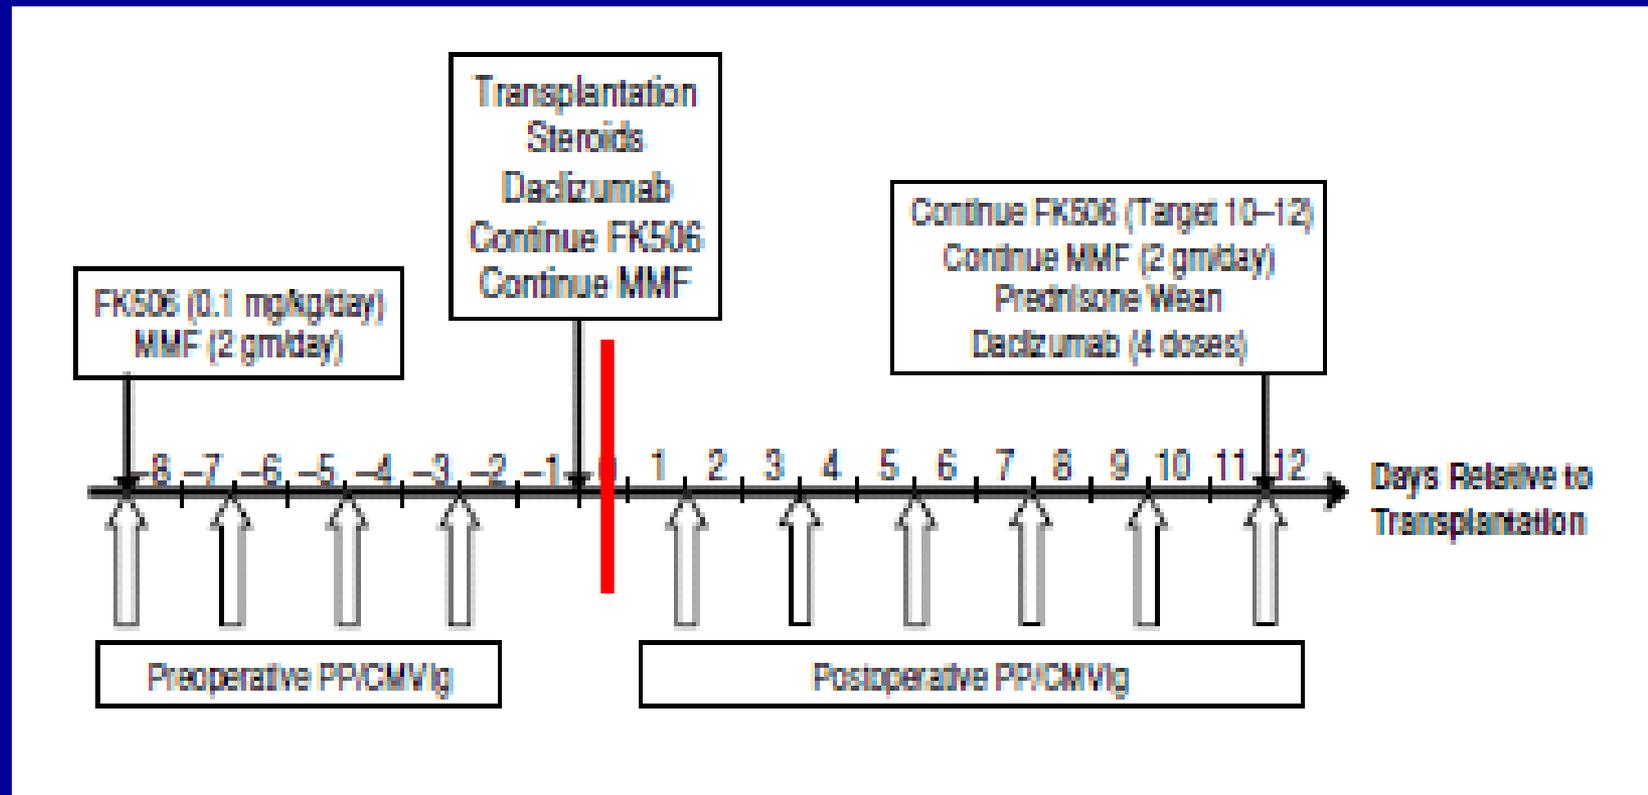

## Summary and Conclusion

- High dose IVIg, although slower to remove Abs, is an effective desensitization modality for both living and deceased donor transplantation.
- Combined PP + IVIg is highly effective for both HLA and ABO incompatibility but is expensive, time consuming and is not useful unless a transplant is imminent.
- Both protocols have favorable results in reducing transplant waiting time for highly sensitized ESRD patients
- For highly sensitized patients with a living donor: should try LDPE first and if fails then resort to desensitization. For highly sensitized patients with no donor → National Highly Sensitized Registry.
